(54) Title: A DEVICE AND METHOD FOR LIFTING A SEA-GOING STRUCTURE, FOR INSTANCE A DRILLING PLATFORM

(57) Abstract

A device for lifting a sea-going structure (C), such as a drilling platform consisting of a superstructure (B) and a jacket (J), which device consists of a flotation body (1) such as a boat provided with one or more laterally slideable lifting devices (2), wherein each lifting device (2) is provided with a coupling member (5) for fixing on a part of the substructure which is arranged for movement in all directions relative to the lifting device (2), whereby the device adapts better to the swell and the relative displacement of the flotation body (1) relative to the drilling platform.

A DEVICE AND METHOD FOR LIFTING A SEA-GOING STRUCTURE,
FOR INSTANCE A DRILLING PLATFORM

The invention relates to a device for lifting a sea-going structure, such as a drilling platform consisting of a superstructure and a jacket, which device consists of a flotation body, such as a boat, provided with one or 5 more laterally slidable lifting devices.

According to an earlier proposal by applicant, such a device is embodied with at least four or more jacks, each provided with a lifting device in order to enable raising of the superstructure after navigating the jacks 10 under this superstructure. The drawback to such a jack is the poor adaptability to swell and the relative displacement of the flotation body or flotation bodies relative to the drilling platform. This can result in uncertainties.

15 The invention has for its object to provide a device wherein the above stated drawbacks are obviated and it provides for this purpose a device which is distinguished in that each lifting device is provided with a coupling member for fixing onto a part of the substructure which 20 is arranged for movement in all directions relative to the lifting device.

A coupling member according to the invention is understood to mean that a positive connection takes place between the lifting means and the substructure of the 25 sea-going structure, wherein the freedom of movement is ensured by the omnidirectional connection between the coupling member and the associated lifting device. The coupling member is preferably arranged at the bottom of a pendulum arm construction, which pendulum arm construction 30 is suspended pivotally from the lifting device. A better stability of the already lifted part is thus ensured relative to the flotation bodies, which increases safety.

In the preferred embodiment the pendulum arm construction 35 is embodied with two arms arranged at a mutual

distance, the bottom ends of which are coupled to the coupling member on either side for pivoting thereon. This results in even better stability because the pendulum arms will automatically assume the optimum position 5 relative to each other as a consequence of the reactive force generated by the weight of the lifted part of the sea-going structure.

If the substructure of the sea-going structure is assembled from tubes, it is recommended to embody the 10 coupling member as a clamp, for instance a shell-like clamp which, if required, can close and open hydraulically.

The invention further relates to a method for lifting a sea-going body, wherein use is made of the above 15 stated device. The method according to the invention is distinguished in that

- the flotation body is placed adjacently of the sea-going body,
 - the coupling member of each lifting device under 20 the superstructure is fixed to the substructure,
 - the or each lifting cylinder of the lifting device is energized,
 - the substructure elements such as the tubes are separated,
- 25 - the superstructure is lifted from the substructure and set down onto a transport vessel such as a pontoon.

The method can also be used to lift the remaining part of the sea-going structure, i.e. the substructure, once the superstructure has first been removed. This 30 substructure has a considerable length and to this end the invention therefore proposes to fix the coupling member of each lifting device to the upper end part of the substructure,

- to lift the substructure,
- to release the coupling members successively in a predetermined sequence and fix them to a lower part of the substructure by relieving the lifting cylinder,
- to then energize the relevant lifting cylinder again in a predetermined sequence,

with a coupling member 5 which can be fixed to any of the tubes of the sea-going structure.

The sea-going structure is embodied with a super-structure B and a substructure or jacket J.

- 5 The whole structure must be removed from the seabed Z and for this purpose the structure is separated into parts and carried away.

- In the shown embodiment of fig. 1, the flotation bodies 1 are arranged on either side with the associated 10 lifting means.

- After fixing of the coupling members 5 the tube construction of jacket J can be separated at the planes of section D, whereafter superstructure B is carried upward by energizing lifting cylinders 4 simultaneously 15 with draining of ballast liquid out of the flotation bodies 1, see fig. 2.

- After navigating away from jacket J, a pontoon P can be guided between the flotation bodies 1 as according to 20 fig. 3, and superstructure B can be set down with a portion of the substructure onto pontoon P by relieving lifting cylinders 4.

- Flotation bodies 1 are then re-placed on either side of the remaining jacket part and the coupling members can be fixed at a random position along the vertical tube 25 parts. By once again energizing lifting cylinders 4 the jacket is raised from the seabed Z and, by subsequently releasing the coupling members 5 one by one and re-ar- 30 ranging them at a lower position along the tubular stand- ing parts of the jacket, this latter can be carried upward each time through a determined height, for in- stance in steps of three metres or the like, as shown in fig. 5.

- Raising of the jacket can go so far that the under- 35 side can be carried above a pontoon P and set down there- on. In the case of a very high jacket it is recommended to separate the bottom part in each case from the part of the device suspended in the coupling members, whereafter the top part can be dropped onto the pontoon. This pro- cture can take place repeatedly until the jacket has been

reduced in height such that it can be carried away safely on pontoon P.

There now follows a description of the coupling members suspended in a pendulum construction according to 5 the invention which is fixed to lifting device 2.

Fig. 6-8 show the coupling member 5 in the form of a clamp consisting of two half-shell parts 10, 11 which can close onto each other in random manner, for instance by hydraulic cylinders (not shown) or in other manner by 10 means of a bolt connection. The clamping force is sufficient to prevent shifting in vertical direction along the tubes of the structure C. If desired, a collar can be welded round the tube (not shown) at the top of the clamp in order to avoid the above mentioned shifting.

15 One of the shell parts 10 or 11 of the clamp is provided with ears 12, each of which is embodied with a ball joint 13 to which the bottom end of a pendulum arm 14 is coupled.

The upper end of each pendulum arm 14 is likewise 20 provided with a ball joint 15 which is received in a fork-like end part 16 of lifting cylinder 4. The fork-like end part 16 is itself provided with a coupling plate 17 for receiving the upper end hinge part 18 of a coupling rod 19. The coupling rod is connected pivotally at 25 20 to lifting device 2. The other end of lifting cylinder 4 is likewise connected pivotally to the lifting device at 21.

Fig. 6a, b, c show diverse height positions which can be reached by relieving or energizing the lifting 30 cylinder 4. Fig. 6a shows the highest position, wherein coupling rod 19 has an upward directed position and wherein the pendulum arm 14 moves to the left compared to the middle position according to fig. 6b. The low position is shown in fig. 6c. The difference in height between the positions 6a and 6c can be for instance three metres.

Fig. 7 shows a position which starts from the middle position, fig. 6b, but wherein the flotation body 1 is shifted relative to the structure C such that pendulum

arm 14 will take up a position clearly moving to the right.

This position is possible without problem due to the ball joints 13 respectively 15. An outward moving position of pendulum arm 14 is of course also possible.

Fig. 8 shows a position wherein both cylinders 4 assume the same position and wherein the pendulum arms 14 lie symmetrically relative to the axis of the tube of structure C. A difference can be seen in fig. 8b, wherein tube C has shifted to the right relative to cylinders 4, this being possible because the cylinders are extended to a greater or lesser degree and wherein the ball joints 15 allow pivoting of pendulum arms 14. Here also, considerable movements are possible in the order of magnitude of two metres.

It will be apparent from the foregoing that due to the flexible suspension of coupling member 5 relative to flotation bodies 1 the stability of the raised part is increased. Relevant here is the self-correcting design of the pendulum arm construction, since the four clamping members engaging on the corner posts of the jacket C automatically adjust to the most favourable position as a result of the force of gravity. The flotation bodies 1 are also set into the correct position relative to the structure as a result of the force of gravity. Possible variations resulting from the influences of the swell on flotation bodies 1 can be overcome easily.

The invention is not limited to the above described embodiment.

The coupling members 5 can be embodied in any suitable manner, for instance as elements which are welded fixedly to the tubes of structure C. What is essential herein is the mobility in all directions of pendulum arms 14 as a result of ball joints 13 respectively 15.

The lifting device 2 can likewise be embodied in random manner, wherein more than one lifting cylinder 4 can be envisaged.

CLAIMS

1. Device for lifting a sea-going structure, such as a drilling platform consisting of a superstructure and a jacket, which device consists of a flotation body such as a boat, provided with one or more laterally slid able lifting devices, characterized in that each lifting device is provided with a coupling member for fixing onto a part of the substructure which is arranged for movement in all directions relative to the lifting device.
- 5 2. Device as claimed in claim 1, characterized in that the coupling member is arranged at the bottom of a pendulum arm construction, which pendulum arm construction is suspended pivotally from the lifting device.
- 10 3. Device as claimed in claim 2, characterized in that the pendulum arm construction is embodied with two arms arranged at a mutual distance, the bottom ends of which are coupled to the coupling member on either side for pivoting thereon.
- 15 4. Device as claimed in claim 3, characterized in that the upper end of each pendulum arm is coupled for pivoting in all directions to a lifting cylinder of the lifting device.
- 20 5. Device as claimed in any of the foregoing claims, wherein the substructure is a structure assembled from tubes, characterized in that the coupling member is embodied as a clamp for placing round a tube of the substructure.
- 25 6. Method for lifting a sea-going body, such as a drilling platform, making use of a device as claimed in any of the foregoing claims, characterized in that
 - 30 - the flotation body is placed adjacently of the sea-going body,
 - the coupling member of each lifting device under the superstructure is fixed to the substructure,
 - the or each lifting cylinder of the lifting device
- 35 is energized,

CLAIMS

1. Device for lifting a sea-going structure, such as a drilling platform consisting of a superstructure and a jacket, which device consists of a flotation body such as a boat, provided with one or more laterally slidable lifting devices, **characterized in that** each lifting device is provided with a coupling member for fixing onto a part of the substructure which is arranged for movement in all directions relative to the lifting device.
5
2. Device as claimed in claim 1, **characterized in that** the coupling member is arranged at the bottom of a pendulum arm construction, which pendulum arm construction is suspended pivotally from the lifting device.
10
3. Device as claimed in claim 2, **characterized in that** the pendulum arm construction is embodied with two arms arranged at a mutual distance, the bottom ends of which are coupled to the coupling member on either side for pivoting thereon.
15
4. Device as claimed in claim 3, **characterized in that** the upper end of each pendulum arm is coupled for pivoting in all directions to a lifting cylinder of the lifting device.
20
5. Device as claimed in any of the foregoing claims, wherein the substructure is a structure assembled from tubes, **characterized in that** the coupling member is embodied as a clamp for placing round a tube of the substructure.
25
6. Method for lifting a sea-going body, such as a drilling platform, making use of a device as claimed in any of the foregoing claims, **characterized in that**
30
 - the flotation body is placed adjacently of the sea-going body,
 - the coupling member of each lifting device under the superstructure is fixed to the substructure,
 - the or each lifting cylinder of the lifting device
35 is energized,

- the substructure elements such as the tubes are separated,
 - the superstructure is lifted from the substructure and set down onto a transport vessel such as a pontoon.
- 5 7. Method as claimed in claim 6, characterized in that
- the coupling member of each lifting device is fixed to the upper end part of the substructure,
 - the substructure is lifted,
- 10 - the coupling members are released successively in a predetermined sequence and fixed onto a lower part of the substructure by relieving the lifting cylinder,
- the relevant lifting cylinders are then energized again in a predetermined sequence,
- 15 - the raised substructure is set down onto a transport vessel.
8. Method as claimed in claim 7, characterized in that after the substructure has been set down onto the vessel the lower part is separated each time.
